

Distribution Box Air Switch Circuit Configuration

Overview

With this configurator, electricians can have the complete parts list, the assembly and wiring diagram and the corresponding nameplate for their project created.

Key Takeaways

An air switch in a distribution box is typically configured as the main protective device, with its input connected to the incoming supply and its output feeding downstream MCBs or RCCBs for individual circuits.

Overview of Air Switch in Distribution Boxes

An air switch is a low-voltage circuit breaker that automatically disconnects the circuit when the current exceeds its rated value, using air as the medium to extinguish the arc generated during tripping. It provides overcurrent and short-circuit protection and is commonly used as the main switch in residential and commercial distribution boxes.

Typical Circuit Configuration

In a single-phase distribution box, the configuration generally follows this sequence:
Incoming Supply: Phase (L) and Neutral (N) wires enter the distribution box. Main Air Switch (Double Pole MCB): The incoming supply is connected to a double-pole MCB, which acts as the main switch. This device handles the total load and provides primary protection.

Residual Current Device (RCCB/RCBO): The output of the main air switch is connected to an RCCB or RCBO for earth leakage protection.

The RCC

B protects multiple downstream circuits, while RCBOs provide combined overcurrent and residual-current protection per circuit. Outgoing Circuit Protection (MCBs): From the RCCB or RCBO, the phase and neutral are distributed to single-pole or double-pole MCBs for individual loads.

Each MC

B is selected based on the load type, conductor size, and installation rules. Busbars and Links: Phase busbars distribute power to MCBs, while neutral and earth bars provide common connection points for neutral and protective earth conductors. Earth and Surge Protection: The earth bar is connected to the building's grounding system, and surge protective devices (SPDs) may be installed for transient voltage protection.

Wiring Notes

Phase and Neutral Connections: For double-pole MCBs, both phase and neutral are connected through the device. For single-pole MCBs, only the phase is switched, while neutral is linked to the neutral bar. Load Connections: Each outgoing load is connected to the output terminals of the respective MCB, with neutral and earth connected to the neutral and earth bars.

Safety Considerations: Always ensure the distribution box is de-energized before wiring. Proper labeling, spacing, and adherence to local electrical codes are essential.

Summary

The air switch serves as the main protective device, feeding downstream RCCBs or RCBOs, which in turn supply individual MCBs for each circuit. This layered protection ensures overcurrent, short-circuit, and earth leakage protection, while busbars and neutral/earth bars provide organized distribution and grounding. Proper configuration and adherence to standards like IEC 61439 and local codes are critical for safety and reliability.
