Does the fiber optic cable go into the terminal box and then come out again

Overview

Illustration of How to Connect the Terminal box in FTTH The outdoor optical fiber cable is connected to the terminal box. The purpose is to fuse the optica.

Key Takeaways

Yes, a fiber optic cable enters the terminal box, is terminated or spliced inside, and then the signal is routed out through pigtails or jumpers.

How It Works

A fiber optic terminal box serves as a junction point where incoming optical cables are organized, protected, and connected to outgoing fibers. When a fiber optic cable arrives at the terminal box, it is secured inside the box and the individual fiber cores are either fusion spliced or mechanically connected to pigtails or adapters within the box. These pigtails then provide the interface for connecting to network equipment or other fiber lines.

Cable Entry and Exit

Entry: The incoming fiber optic cable is fed into the terminal box through a cable gland or entry port, which provides strain relief and environmental protection. Internal Management: Inside the box, fibers are carefully routed around spools or trays to maintain the minimum bend radius and prevent damage. Any excess fiber from the incoming cable or pigtails can be stored neatly within the box.

Exit: After termination or splicing, the fiber signal exits the box via jumpers or patch cords that connect to devices such as optical transceivers or distribution panels. This ensures the optical signal continues to the next point in the network. Purpose of the Terminal BoxThe terminal box is not just a pass-through; it provides several critical functions: Protection: Shields delicate fibers from bending, dust, and handling damage.

Organization: Keeps fibers and splices neatly arranged for easy maintenance. Connectivity: Allows multiple fibers to be terminated, spliced, and routed to different outputs, supporting branched or straight-through configurations. In summary, the fiber optic cable does enter the terminal box, is terminated or spliced inside, and then the signal is routed out through pigtails or jumpers, making the box a central point for both protection and distribution of optical fibers.
